

# MODULES IN PYTHON

# INTRODUCTION

A module is a single Python file (.py) that contains Python code: functions, classes, variables, and even runnable code.

## **Purpose:**

To **organize code**, increase reusability, improve readability, and avoid duplication.

## **Why Use Modules?**

- ❑ Code reusability
- ❑ Better organization (large projects become manageable)
- ❑ Separation of concerns
- ❑ Easier testing and maintenance

# CREATING A MODULE

## Creating a module

**Step 1: Create a file named mymodule.py**

**Step 2 : Define your code**

```
# mymodule.py
```

```
def greet(name):  
    return f'Hello, {name}!'
```

```
def add(a, b):  
    return a + b
```

```
pi = 3.14159
```

# IMPORTING A MODULE

## Using import statement

### Method - 1

Syntax: **import module**

Example : **import mymodule**

Note : Here Python imports only the module, NOT all its names into your current namespace.

So, everything inside mymodule is loaded, but not directly accessible unless you use the module prefix:

Example: **print(mymodule.add(10,5))**

**print(mymodule.greet('QUEST'))**

# IMPORTING A MODULE

## Method - 2

Syntax: **from module\_name import name1, name2, name3, ...**

Example : **from math import sqrt, pi**

Note :

- ❑ Here only sqrt and pi are imported
- ❑ You can use them directly
- ❑ Does NOT import the entire module

Example : **print(sqrt(16))**

**print(pi)**

# IMPORTING A MODULE

## Method - 3

Syntax: **from module\_name import \***

Example : **from math import \***

Note :

- ❑ This imports **all public functions, variables & classes** of the module into your namespace directly.
- ❑ No need for `math.sqrt`, just `sqrt(16)`
- ❑ Can cause **name conflicts**
- ❑ **Hard to debug**
- ❑ **Not recommended in real project**
- ❑ **Only safe for small classroom examples**

# IMPORTING A MODULE

## Method - 4

Syntax:

```
from module_name import name1 as alias1,  
name 2 as alias2....
```

Example : **from math import sqrt as s, pi as p**

## Advantages

- ❑ Avoid Name Conflicts
- ❑ Shorter and Cleaner Code
- ❑ Improves Readability & Meaning
- ❑ Avoid Overwriting Built-ins
- ❑ Aliases only rename in your program (not globally)

## Notes / cautions:

- ❑ Use meaningful aliases
- ❑ Don't overuse
- ❑ Follow community standards
- ❑ Alias only when necessary

# TYPES OF MODULES IN PYTHON

# Math Module

| Method                         | Description                   | Example                        |
|--------------------------------|-------------------------------|--------------------------------|
| <code>math.sqrt(x)</code>      | Square root of x              | <code>math.sqrt(25)</code>     |
| <code>math.pow(x, y)</code>    | x raised to power y           | <code>math.pow(2, 3)</code>    |
| <code>math.factorial(x)</code> | Factorial of x                | <code>math.factorial(5)</code> |
| <code>math.ceil(x)</code>      | Round UP to nearest integer   | <code>math.ceil(4.1)</code>    |
| <code>math.floor(x)</code>     | Round DOWN to nearest integer | <code>math.floor(4.9)</code>   |
| <code>math.trunc(x)</code>     | Remove decimal part           | <code>math.trunc(5.8)</code>   |
| <code>math.fabs(x)</code>      | Absolute value (float)        | <code>math.fabs(-7.5)</code>   |

provides a wide range of **mathematical functions and constants** for performing mathematical operations

It contains:

- ❑ **Mathematical functions** (e.g., `sqrt`, `sin`, `cos`, `log`, `ceil`, `floor`)
- ❑ **Mathematical constants** (e.g., `pi`, `e`, `tau`, `inf`, `nan`)

# datetime module

- ❑ Used to work with **dates, times, and time intervals**.
- ❑ It allows you to create, manipulate, format, and perform arithmetic on **dates, times, timestamps, and durations**.

## 1. Classes for working with date & time

- ❑ `date` → works with only **year, month, day**
- ❑ `time` → works with only **hour, minute, second**
- ❑ `datetime` → combines **date & time**
- ❑ `timedelta` → represents **difference between two dates or times**

## 2. Functions for current date & time

- ❑ `datetime.now()` → current date & time
- ❑ `date.today()` → current date

## 3. Formatting / Parsing functions

- ❑ `strftime()` → convert datetime to string
- ❑ `strptime()` → convert string to datetime

## 4. Time zone support

- ❑ `timezone` class → create timezone-aware datetime values

# Strftime Formatting codes

| Code      | Meaning                  | Example Output |
|-----------|--------------------------|----------------|
| <b>%Y</b> | Year (4 digits)          | 2025           |
| <b>%y</b> | Year (2 digits)          | 25             |
| <b>%m</b> | Month (01–12)            | 03             |
| <b>%B</b> | Full month name          | March          |
| <b>%b</b> | Abbreviated month name   | Mar            |
| <b>%d</b> | Day of month (01–31)     | 09             |
| <b>%A</b> | Full weekday name        | Sunday         |
| <b>%a</b> | Abbreviated weekday name | Sun            |
| <b>%H</b> | Hour (00–23)             | 17             |
| <b>%I</b> | Hour (01–12)             | 05             |
| <b>%p</b> | AM/PM                    | PM             |
| <b>%M</b> | Minute (00–59)           | 42             |

# Strftime Formatting codes

| Code      | Meaning                         | Example Output          |
|-----------|---------------------------------|-------------------------|
| <b>%S</b> | Seconds (00–59)                 | 33                      |
| <b>%f</b> | Microseconds                    | 548321                  |
| <b>%z</b> | UTC offset                      | +0530                   |
| <b>%Z</b> | Timezone name                   | IST                     |
| <b>%j</b> | Day of year (001–366)           | 123                     |
| <b>%U</b> | Week number (Sunday first)      | 22                      |
| <b>%W</b> | Week number (Monday first)      | 21                      |
| <b>%c</b> | Full date & time (locale based) | Sun Mar 9 17:42:00 2025 |
| <b>%x</b> | Locale date                     | 03/09/25                |
| <b>%X</b> | Locale time                     | 17:42:00                |

# Random Module

- ❑ Used to generate **pseudo-random numbers**
- ❑ Example choosing random items, shuffling sequences, generating random integers, floats, and making random selections.

| Method                              | Description                                                                    |
|-------------------------------------|--------------------------------------------------------------------------------|
| <b>random()</b>                     | Returns a random float between <b>0.0 and 1.0</b> .                            |
| <b>randint(a, b)</b>                | Returns a random integer between <b>a and b (both included)</b> .              |
| <b>randrange(start, stop, step)</b> | Returns a random number from the given range (stop excluded).                  |
| <b>uniform(a, b)</b>                | Returns a random <b>float</b> between <b>a and b</b> .                         |
| <b>choice(sequence)</b>             | Returns a <b>random element</b> from a non-empty sequence.                     |
| <b>choices(sequence, k=n)</b>       | Returns a list of <b>k randomly selected elements</b> (with replacement).      |
| <b>shuffle(list)</b>                | Randomly reorders the elements of a list <b>in place</b> .                     |
| <b>sample(population, k)</b>        | Returns <b>k unique random elements</b> from a sequence (without replacement). |
| <b>seed(n)</b>                      | Sets the seed value for reproducing the same random results.                   |
| <b>betavariate(alpha, beta)</b>     | Returns a random float from the <b>beta distribution</b> .                     |
| <b>expovariate(lambd)</b>           | Returns a random float from an <b>exponential distribution</b> .               |
| <b>gauss(mu, sigma)</b>             | Returns a random float from a <b>Gaussian (normal) distribution</b> .          |
